### Question 1

- (a) Given a very large sample size  $n$  and a small number of predictors  $p$ , an inflexible method would be better than a flexible one, since the risk of overfitting is less.
- (b) For the same reasons as (a), a flexible method would yield better results for small  $n$  and large  $p$ .
- (c) A flexible method would yield better results, since non-linear functions cannot be accurately modelled by linear functions.
- (d) If there is high variance in the error terms, an inflexible method would be better, since a flexible method would introduce even more variance in the values of  $\hat{f}$ .

### Question 2

- (a) This is a classification problem, since we are trying to identify a qualitative trend in the data. It is an inference problem, since we are not trying to estimate future values of  $f$ . In this case, we have  $n = 500$  and  $p = 4$ .
- (b) This is a classification problem, since we are trying to classify the product as either a success or a failure. It is also a prediction problem, since we are looking to estimate a future output. We have  $n = 20$  and  $p = 14$ .

- (c) This is a regression problem since we have quantitative data and assume that it fits some function  $f$ , which we are attempting to estimate. Since this is a future estimate, it is a prediction problem. We have  $n = 52$  and  $p = 4$ .
